

Does the mCH / MeCP2 correlation depend on histone mark context?

Heterogeneity of the four correlations: chi-squared = 34.78, df = 3, $p = 1.36\text{e-}07$ | pooled rho = 0.205 over 9,517 genes

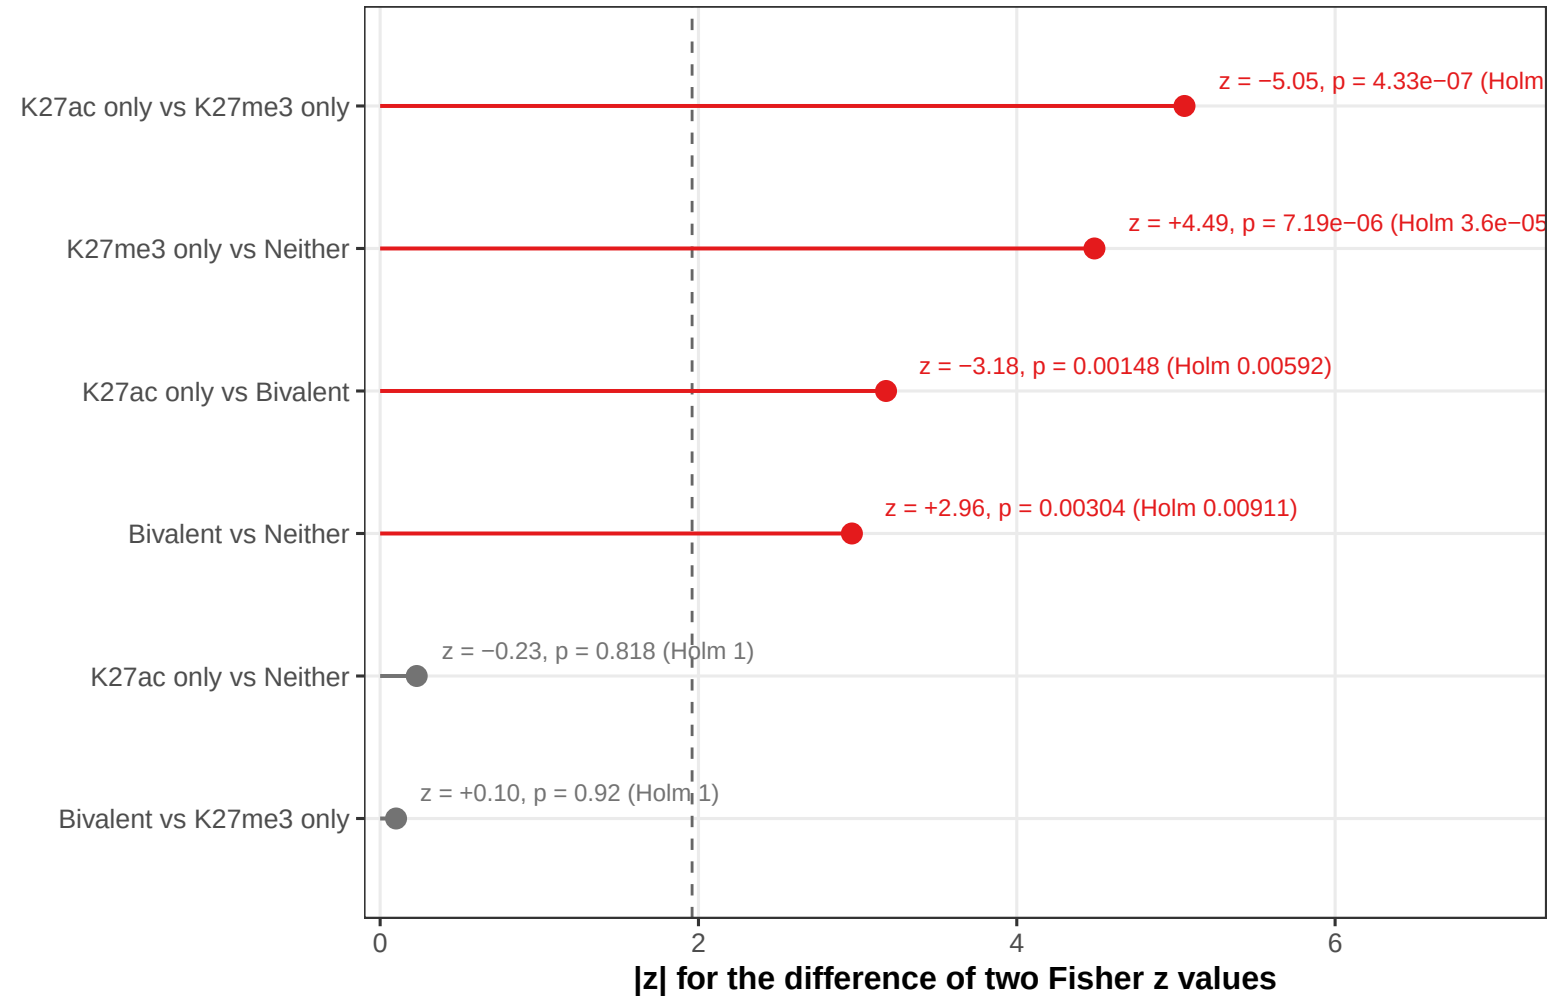

Spearman rho per mark category

95% confidence interval from the Fisher z transform, $\text{var}(z) = 1.06/(n-3)$

Pairwise Fisher z tests between categories

Dashed line is the two-sided 5% critical value, $|z| = 1.96$

● Holm $p < 0.05$ ● Holm $p \geq 0.05$
